Research Topic:

SafeSight. To create a physical system that can take in images from fisheye cameras, process it, and then using models to check for any dangerous situations. That would mean the system would be have blindspot detection, rear and forward collision warning, lane drift warning, and a screen that could display position of other cars relative to the main car and be the warning system.

March 24th

Organized my files. Worked on lane departure

March 26th

Worked on lane departure

Spring Break

Worked on lane departure. Everything for it is finished now other than the last part: building on top of finding the lane each frame I want it to be able to match the frame or like compare it to the lane from the previous frames in order to get more consistent lane markings.

Timeline

Date	Goal	Met?
Today minus 2 weeks	Detect distances of cars/find dataset with continuous frames	Done
Today minus 1 week	Finish up collision warning	Done
This week	Finish up if needed/start working on lane drift	Done
Today plus 1 week	work on lane drift	TBD
Today plus 2 weeks	Work on lane drift	TBD

Reflection

I finished most of the lane departure warning over spring break, because I wanted to make sure I had enough time to make the visual part of the project that showcases where the cars are. I finished most of lane departure but having the lanes be compared to previous frames is the last major thing left for that. I tried comparing the lanes by averaging out the lanes from the previous frames and the current frame with the current one having a bit more weight to it, and it didn't really work out it would still create some very odd lanes. I don't really know how I should approach it so I will probably start researching that and testing out solutions that others have made.
